

Shining the Light on Black Basta

06 June 2022 By [RIFT: Research and Intelligence Fusion Team](#)

◆ Research ◆ Threat Intelligence ◆ Digital Forensics and Incident Response (DFIR)

This research was conducted by **Ross Inman** (@rdi_x64) and **Peter Gurney** from NCC Group Cyber Incident Response Team. You can find more here [Incident Response – NCC Group](#)

Summary

tl;dr

This blog post documents some of the TTPs employed by a threat actor group who were observed deploying Black Basta ransomware during a recent incident response engagement, as well as a breakdown of the executable file which performs the encryption.

A summary of the findings can be found below:

- Lateral movement through use of Qakbot.
- Gathering internal IP addresses of all hosts on the network.
- Disabling Windows Defender.
- Deleting Veeam backups from Hyper-V servers.
- Use of WMI to push out the ransomware.
- Technical analysis of the ransomware executable.

Black Basta

Black Basta are a ransomware group who have recently emerged, with the first public reports of attacks occurring in April this year. As is popular with other ransomware groups, Black Basta uses double-extortion attacks where data is first exfiltrated from the network before the ransomware is deployed. The threat actor then threatens to leak the data on the "Black Basta Blog" or "Basta News" Tor site. There are two Tor sites used by Black Basta, one which leaks stolen data and one which the victims can use to contact the ransomware operators. The latter site is provided in the ransom note which is dropped by the ransomware executable.

The first used the batch script d.bat which was deployed locally on compromised hosts and executed the following PowerShell commands:

- powershell -ExecutionPolicy Bypass -command "New-ItemProperty -Path 'HKLM:SOFTWARE\Policies\Microsoft\Windows Defender' -Name DisableAntiSpyware -Value 1 -PropertyType DWORD -Force"

- powershell -ExecutionPolicy Bypass -command "Set-MpPreference -DisableRealtimeMonitoring 1"
- powershell -ExecutionPolicy Bypass Uninstall-WindowsFeature -Name Windows-Defender

The second technique involved creating a GPO (Group Policy Object) on a compromised Domain Controller which would push out the below changes to the Windows Registry of domain-joined hosts:

Qakbot was the primary method utilised by the threat actor to maintain their presence on the network. The threat actor was also observed using Cobalt Strike beacons during the compromise.

Prior to the deployment of the ransomware, the threat actor established RDP sessions to Hyper-V servers and from there modified configurations for the Veeam backup jobs and deleted the backups of the hosted virtual machines.

An encoded PowerShell command was observed on one of the compromised Domain Controllers which, when decoded, yielded a script labelled as Invoke-TotalExec that provided the ability to spread and execute files over the network using WMI (Windows Management Instrumentation). The script was used to execute a command that would copy the file to the IP address of the server and then execute the file. The file was then executed on the server that

The next operation creates a new registry key with the name .basta under HKEY_CLASSES_ROOT and sets the DefaultIcon subkey to display the dropped .ico file. This results in files given a .basta file extension inheriting the Black Basta logo. The registry key can be seen below in Figure 5.
