

Hitching a ride with Mustang Panda

by **Threat Intelligence Team** — December 2, 2022 — 31 min read

Avast discovered a distribution point where a malware toolset is hosted, but also serves as temporary storage for the gigabytes of data being exfiltrated on a daily basis, including documents, recordings, and webmail dumps including scans of passports from Asian, American and European citizens and diplomats applying for Burmese visas, from Burmese human rights activists and Burmese government institutions.

We recently came across a peculiar sample – a stager we believe is being used by Mustang Panda. The stager led us to the group's distribution point, where we found malicious toolsets. We have analyzed the malware and were able to see relations between various campaigns that have been described by other cybersecurity firms over the course of the last years. Based on publicly published research and our own investigations, we can say with high confidence that the modus operandi and the malicious toolset show a strong link to a group related to Mustang Panda, which has previously been reported as a Chinese APT group. The group has been known for gathering intelligence on [Mongolia](#), and further [Asian countries](#), and most recently was suspected of targeting [European entities](#).

The distribution point, an FTP server, is also used as a transition point for exfiltrated victim data, before the data is moved to an unknown location. We continue to observe new data being uploaded and moved from the point, meaning the campaign is still active, and has been going on for some time. Gigabytes of data are moved around, and the amount of data indicates severe compromise of many high-profile targets in Myanmar. The data types include various office documents and PDFs, stolen browser profiles, webmail dumps and even sound recordings. Browsing profiles were also extracted which can provide access to other infrastructures, services, and private data of the victims. Most of the stolen data seems to be in Burmese making it challenging to analyze. The sensitive data is mainly being collected from devices used by the Myanmar government, state administration, police, army, significant public organizations, or companies, and includes data related to diplomatic meetings, court hearings, military information, contracts and more.

Disclaimer: We have only seen partial snapshots of the exfiltrated data as they are deleted shortly after being moved from the distribution point, so it should be noted that the information we have on victims may be inaccurate or incomplete. Most of the documents are in Burmese, therefore, a language barrier has also to be taken into account. Finally, due to the limited scope and the sheer volume of the data, some assumptions had to be made during the research process. We have reached out to local CERTs, informing them of our findings.

Victimology

Nearly all of the victims have close ties to Myanmar and it seems that both the Burmese government and opposition groups are being targeted. We have seen data originating from various departments of several Burmese ministries. Even the Office of the State Administrative Council has been targeted. The government breach is not isolated to Myanmar – we have also seen Myanmar embassies among targets, for example, the embassy in Serbia. The data also contained dumps of a mailbox used to communicate in 2016 and 2017, as well as in 2020 with visa applicants from all around the world. These messages contained scans of passports from citizens and diplomats from various countries, such as China, Australia, Czech Republic, France, Israel, Netherlands, UK, and USA.

After such an extensive list of targets, it ought to be little surprise that Myanmar Police Force is also among the targets. Even some higher profile departments, such as the Office of the

Information Police Chief or the Department of Special Investigation, seem to have been breached. Tatmadaw (Myanmar Armed Forces) is also not an exception – we have seen victims from the Bureau of Air Defense, Myanmar Army Engineering, and the United Wa State Army.

Political NGOs and the government's opposition are also on the list of victims. It is possible that the list is even more extensive as we may not be able to find a straightforward association to said organizations as we would expect more common usage of personal computers or computers that are not centrally maintained by an IT department. We have seen data from devices belonging to the Karen National Union, Center for Diversity and National Harmony, National Reconciliation and Peace Centre, Ethnic Nationalities Affairs Center, and even the Union Civil Service Board.

Exfiltrated Data

The most common file types being exfiltrated by the group are Microsoft Office documents (.docx, .xlsx, .pptx, etc.), PDF documents, and plain text files. Other file types exfiltrated include audiovisual data in various forms, including sound recordings (.mp3), and pictures (.jpg, .png, etc.) or drawings. Emails, including entire conversations are also exfiltrated.

It appears that the attackers are also looking for and collecting data from browser profiles from various web browsers, e.g. Chrome, Firefox, Opera, and more, a serious threat to victims' privacy. The stolen browser profiles can provide access to other infrastructures, services, and the victims' private data of the victims. The attackers are extracting information about browsing history, stored credentials (personal and work), credit cards, used tokens, and valid cookie sessions. Consequently, poorly secured services, such as services without two-factor authentication or without a safe cookie policy, can be easily abused by attackers. Attackers can steal the identity of victims and can use their email, Facebook, Telegram, or other accounts to collect additional information about the victim and their family, friends, and activities.

Highly sensitive data is being collected from victims' computers, and, in most cases, these are computers used by the Myanmar government, state administration, police, army, significant public organizations, or companies. This in some cases included sensitive data and information belonging to international citizens and diplomats who have interacted with targeted departments.

The documents, and audiovisual data being exfiltrated by the group is massive. The files include everything from:

- Email dumps including visa applications and scans of passports belonging to citizens and diplomats from various countries, such as China, Australia, Czech Republic, France, Israel, Netherlands, UK, and USA
- A seating plan for the [meeting between former US Ambassador to the United Nations Bill Richardson and Myanmar's leader, Senior Gen. Min Aung Hlaing](#)
- Myanmar's constitution with proposed changes
- Invitations for diplomatic meetings, meeting programs, calls, and talking points
- Reports, maps, and screenshots from the Signal messaging app related to the UWSA (United Wa State Army)
- Data from the Office of the Chief of Myanmar Air Defense Force, including meeting minutes, full staff/rank lists, photo IDs (some with fingerprints), salaries, personal details of employees' families
- Peace treaty documents
- Interrogation reports
- Contracts
- Court hearings
- Town plans
- Contact information for police officers, including their names, addresses, telephone numbers, and salaries
- Transcripts of meetings around politics, and elections
- Meeting minutes and audio recordings of meetings between Myanmar senior officials (Prime minister, Chairman of State Administrative Council) and the President of Tatarstan
- Military buildings drawings, including munitions storage, oil storage and aerial photos of proposed sites
- International banking records and records and transfers from supporters to a refugee group

Ties to known campaigns

Since getting our hands on the distribution point, we have established links between known campaigns already publicly reported and what we have discovered. This gives us clues as to how resourceful the group may be and will also help us assess its *modus operandi*.

We have found files strongly resembling (or even matching) samples and their relations described in a [blogpost by ESET](#) around the Korplug variant dubbed Hodur. The campaign they described was targeting various government organizations in Mongolia, Vietnam, and Myanmar, along with politically-oriented NGOs. This is in alignment with the victimology of the stolen data we have seen on the distribution point. Hodur was attributed to the Mustang Panda group. The related part of the uncovered toolset we analyzed also contained a USB launcher written in Delphi, similar to the one seen accompanying the Hodur variant of Korplug analyzed by ESET. This installer is responsible for firing up the infection chain leading to a variant of Korplug RAT.

Similarly, we've found similarities to operations attributed to LuminousMoth both in structure and purpose. For instance, we have seen a very similar structure as the one described in [Bitdefender's research](#) on the LuminousMoth group. Namely, the usage of the same binaries for sideloading, same pattern for exfiltration – using RAR for collection and a sideloaded library for exfiltration via Google Drive. Perhaps the most common pattern was the usage of a USB launcher written in Delphi that was attributed to Mustang Panda, which was also described in Bitdefender's research.

In some cases, we have seen some unreliable links to older campaigns such as [Operation NightScout](#), a rather old [KMPlayer supply-chain attack](#), or [Operation Harvest](#). Namely, binaries used for sideloading or names of encrypted payloads matched the ones used in these old campaigns. Nevertheless, the specific payloads differ significantly, so while some of these were attributed to Mustang Panda, the similarity could also be coincidental.

Toolset overview

The storage we have discovered contains many archives with various tools to be downloaded by infected victims. We will use names of these archives to impose basic structure on the data we have found. It is worth noting that these names are partially consistent in successive versions. For instance, we have found an archive *KKL* which was later on accompanied by another version with a slightly different configuration called *KKL1*.

Some archives contained complete toolsets, whereas others only had single purpose tools in them that were meant to be used in connection with other tools; for instance, one contained a keylogger that obviously lacked any exfiltration functionality. This provides a strong indication that the tools are intended to be used modularly. We will build upon that and first talk about the usual Mustang

Panda theme – Korplug. Then we'll get to the more specific tools and end with the single purpose tools. Notably, nearly all the tools, aside from Korplug, its loaders, and Delphi installers, haven't been described before. The RAT written in Go (*JSX*) or the modular backdoor (*US_2*) deserve an extra mention due to their complexity

From the data we have seen, we conjecture that the main exfiltration tools are variants of tools contained in archives named *GDU*, which use Google Drive for the exfiltration. Since we haven't seen any exfiltration tool that uses the distribution point directly and the path on the server of exfiltrated files contains *gd*, we presume that the responsible group uses some other tools to move files from various Google Drives to the distribution point we saw.

A brief look at the toolsets brings up another interesting fact: almost all the files show approximately (up to a few cases within seconds) a seven or eight hour offset between the compilation timestamp and the "last modified" timestamp of the file itself. Since the compilation timestamp is usually in UTC and the archives use the local time for the contents' last modification date, this places us at UTC-8 and UTC-7. Therefore, we presume that the build setup operated in a time resembling Pacific Standard Time (PST) and Pacific Daylight Time (PDT), used on the West Coast of the United States. There are a few caveats – *SE3* and *SE4* contain files that were compiled on November 1, 2021 and still have an eight hour offset even though none of the countries using PST/PDT transitions to PST that early (both USA and Canada transition to PST a few days later).

There is also a file with an obviously spoofed compilation timestamp. *HT3* contains a DLL *Vender.dll* whose compilation timestamp dates more than a month after the last modification date. This further weakens hypotheses that build upon timestamp offsets. Unfortunately, we have no further leads explaining this outlier. The latest version of the uploader (multiUpload.exe), whose usage was spotted at the beginning of June, has a compilation timestamp of January 3, 2020. This is also very likely spoofed as analyses of the previous versions of this tool show clear evolution and, according to their respective timestamps, they were all compiled in April 2021. Not to mention that the corresponding infrastructure was only created at the end of May 2022.

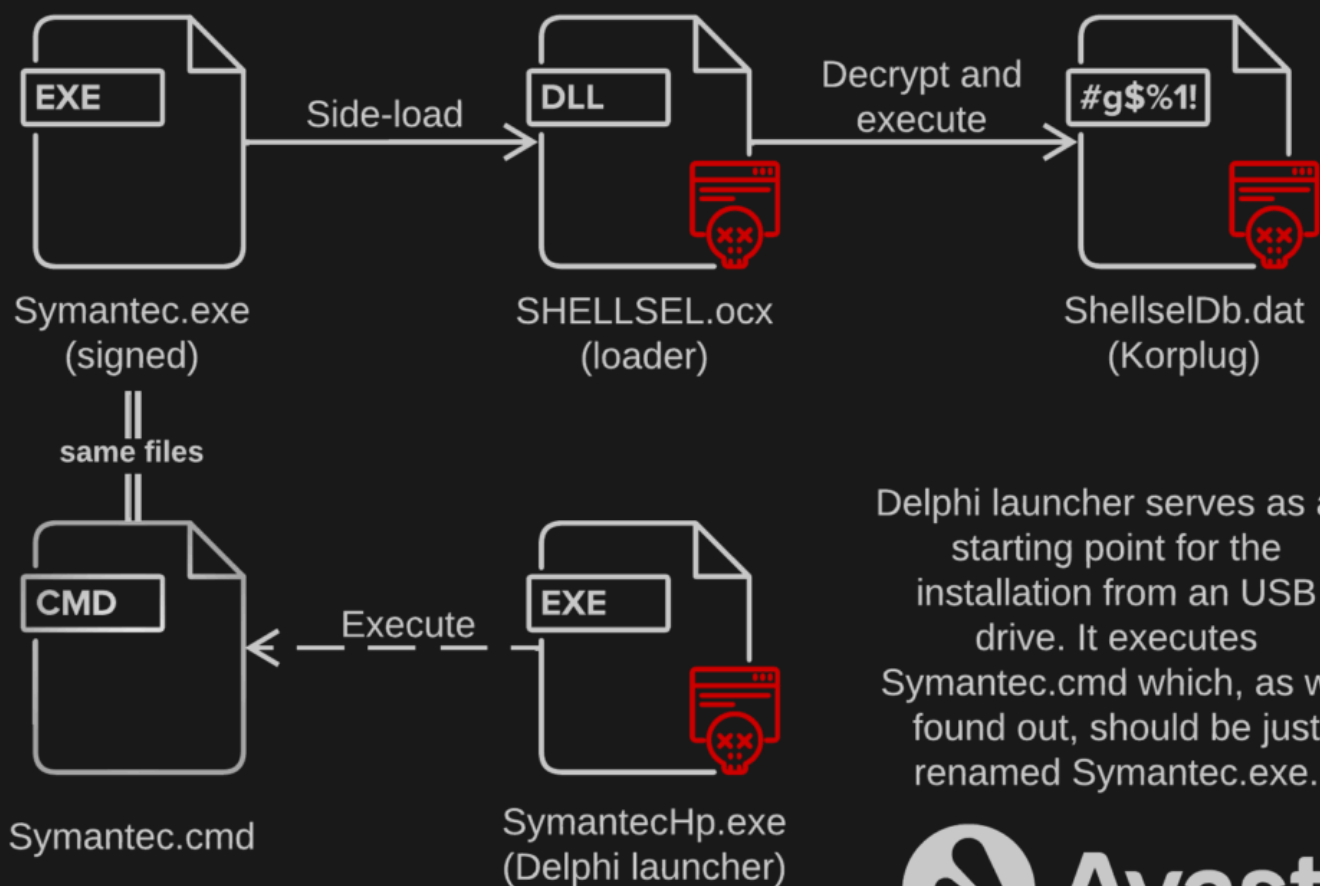

The folder */pub/god*, which contained the toolset archives, was removed on June 25, 2022. On the same day, a new folder */pub/god1* was created with two files to which we didn't have read access.

Two days later, the new folder was gone and */pub/god* appeared again with a subset of the original tools.

Variations on Korplug

The first group of tools that we'll introduce are various versions of Korplug. The binaries used for side-loading were already seen before. Even though the loaders were mostly new, they were rather uninteresting. A common theme was a Delphi binary that served as a launcher to be executed from an infected USB drive. As we've already mentioned, a similar installer was previously seen in campaigns attributed to Mustang Panda. It just executes the Korplug loader from a folder named "*Kaspersky*" that is on the very same USB drive. See the diagram below (based on a toolset from an archive named *BMD*) for more details.

Note the usage of the folder name "*Kaspersky*" and usage of "*Symantec*" in the names of the executables; since the launcher relies on social engineering tricks, it depends on a common strategy using seemingly legitimate file names to dispel any doubts concerning the content.

Delphi launcher serves as a starting point for the installation from an USB drive. It executes Symantec.cmd which, as we found out, should be just renamed Symantec.exe.

Contents of an archive called BMD. Archive YK41 follows the same structure, with ShellSelDb.dat being replaced with hp_ui.xslbcdsj and without the Delphi launcher.

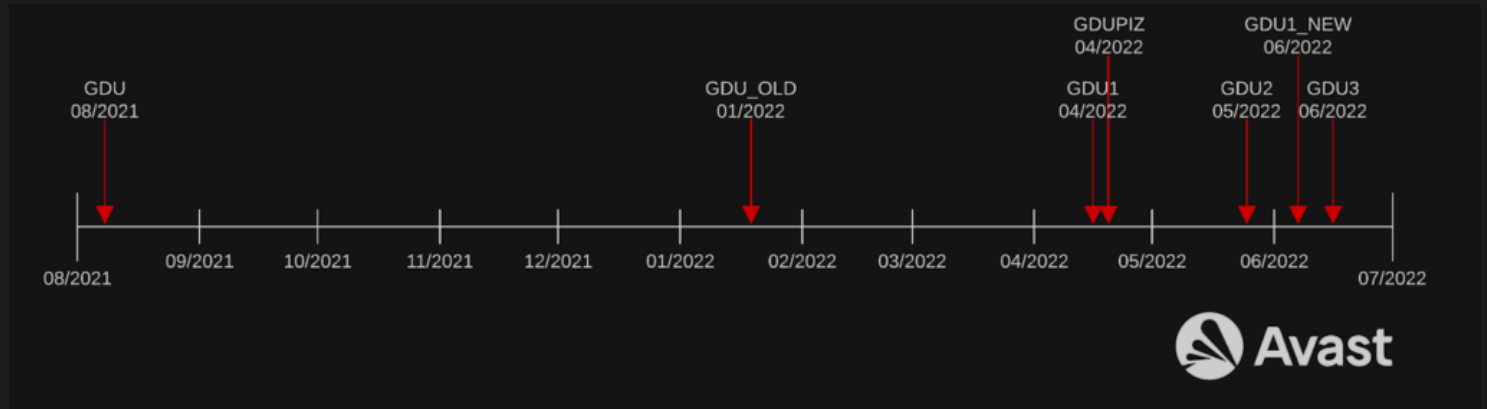

There were also simpler infection chains, containing just a signed clean binary, a loader to be side-loaded, and an encrypted Korplug. These were contained in archives *WD*, *127C*, and *1260M*. The latter interestingly used the *OleView.exe* binary which then side-loaded the *ACLUI.dll* that decrypted and executed *ACLUI.DLL.UI*. The same signed binary, which surprisingly also has the same name of the encrypted payload, was used in the KMPlayer supply-chain attack in 2013. The accompanying research was only published in Chinese, likely due to the attack being limited to a few devices.

Exfiltration toolset

The exfiltrated data on the server in `/pub/gd` folder showed perfect correlation to the data produced by *GDU* toolsets (*GDU_OLD*, *GDU*, *GDU1*, *GDU2*, *GDU1_NEW*, *GDU3*, *GDUIZ*). These tools collect the files on the victim's disk, pack them into an archive whose name is prefixed with the victim's ID and upload that archive onto a Google Drive. We presume that the name *GDU* is an acronym for *Google Drive Uploader*. While the tools themselves were technically rather simple, the exfiltration process and their evolution piqued our interest.

The analysis of the exfiltration process brought up several interesting observations. A few days after May 24, 2022, the day we started systematically monitoring Google Drives used for the exfiltration, we started to see more frequent token changes and new features being implemented. These features mitigated possible downtime caused by the migration to a new token. Since Google Drive has extensive logging functionality and the tokens have to be present on the infected devices, it is only a reasonable expectation that access to these drives is monitored to some extent.

On the contrary, we have not seen such behavior with the distribution point. This could be attributed to the fact that the distribution point is never exposed by the toolsets, which brings us to the assessment that the group presumes the distribution point to be secret or not worth monitoring.

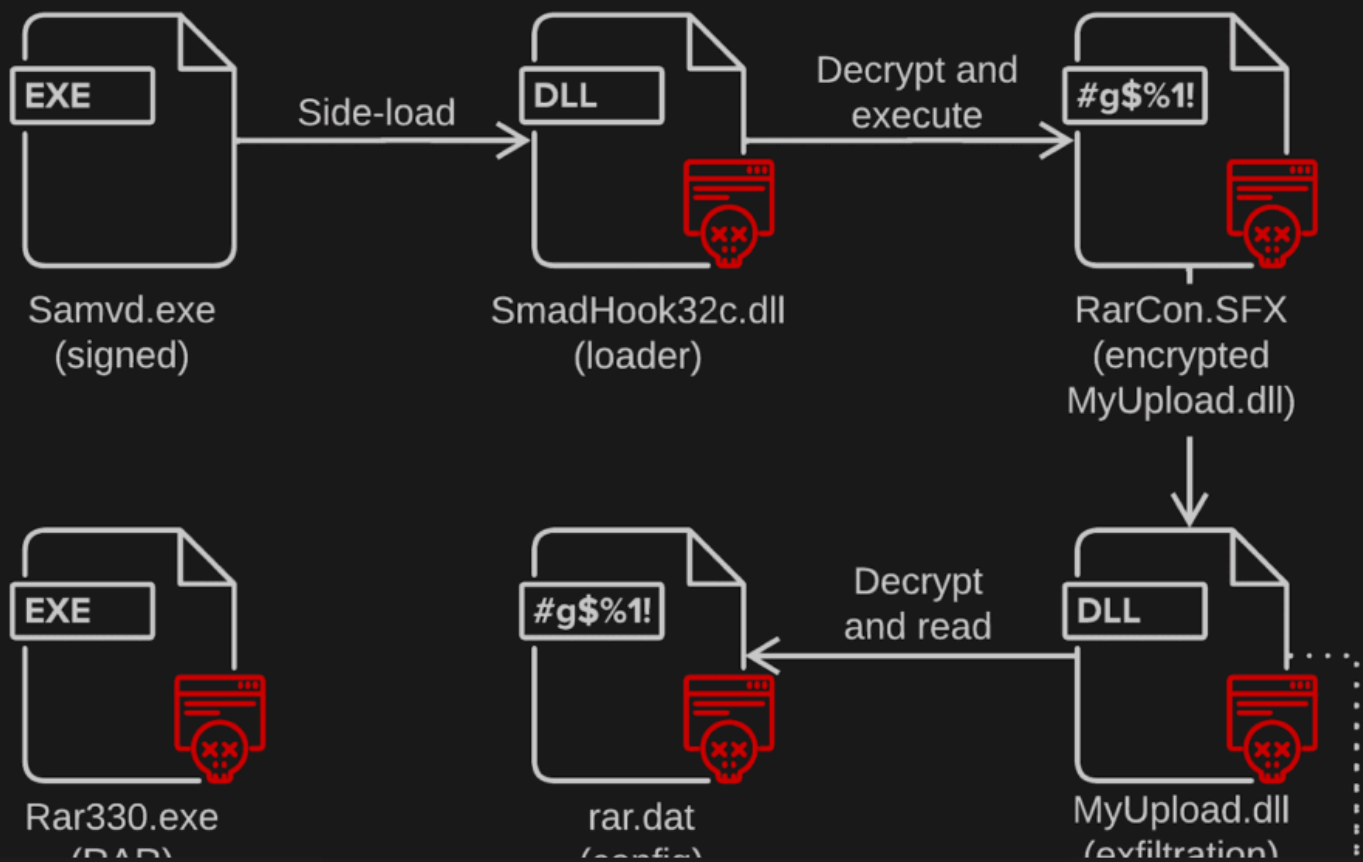

Timeline of GDU exfiltration toolsets

Version overview

The oldest version *GDU* uses RAR executable to collect the data and an encrypted *rar.dat* to store parameters for the RAR binary. Starting from *GDU_OLD*, they migrated to their own collector

piz.exe (this functionality was later moved to a DLL to be side-loaded) and retained an encrypted *rar.dat* where they stored their configuration. These toolsets also rely on two optional configuration files that are backed up by hard-coded values: *token.dat* containing an encrypted token for Google Drive and *time.ini* that contains last execution date along with the victim's ID. The setup and the choice of binaries for side-loading bears resemblance to the LuminousMoth campaigns and tooling.

An archive GDU that contains a version relying on RAR instead of piz.exe for data collection.

The exfiltration process is usually handled by a variant of *MyUpload.dll* that is supplemented by the aforementioned configuration files. Quite recently, a new version of GDU1 has appeared on the

distribution point (which we'll call *GDU1_NEW*) which came with its successor *multiUpload.exe*. *multiupload.exe* eschews hard-coded tokens and makes the exfiltration process more resilient to disruptions.

Archive GDU_OLD that uses its own collector piz.exe to collect potentially interesting files before the exfiltration.

The version we are calling *GDU_OLD* is basically the same as *GDU1* and *GDUPIZ*, the most significant difference being a different PE being used for side-loading. *GDU1* and *GDUPIZ* rely on *CefSub.exe* and subsequently on *CefBrowser.dll* instead of *AtlTracetool.exe*. *GDUPIZ* also uses a slightly different approach to execute the file collection tool *piz.exe* – the version included in this folder is in fact a renamed clean binary *spoololk.exe* which in turn side-loads *vntfx32.dll*. This malicious binary implements the file-collecting functionality formerly contained in *piz.exe*. *GDU2* is basically the same as *GDUPIZ*.

On June 8, 2022, we saw a new *GDU1* toolset on the distribution point. This time *MyUpload.dll* has been upgraded to provide redundancy in the exfiltration process. It no longer uses *token.dat* but rather uses a Github repository as its source for the token. If this fails, there are two backups – one using HTTP PUT to *www.watercaltropinfo[.]com* with Basic HTTP Authorization (*123:123*). The other sends the data via HTTPS POST to *m.watercaltropinfo[.]com*. The collector is the same as in *GDUPIZ*. *GDU3* uses basically the same process but uses different PE for side-loading (*FwcMgmt.exe*).

Tokens

A special chapter is devoted to Google Account tokens that are used in these tools, partially because our research may have forced the group’s hand to refresh the tokens once they discovered that we knew of their Google Drives. The fact that after each token decommission, every client had to have the token updated and that *GDU* toolsets do not have any remote update functionality suggests that these toolsets have to be accompanied by other tools that provide this update functionality. We have noticed a longer delay between the decommissioning of the token from May 29, 2022 and before a replacement token was being distributed. Its distribution coincides with the time a new version of *GDU1_NEW* was released. It’s exactly this version that has introduced new functionality in the exfiltration tool, namely smoother token swapping and failsaves for cases when Google Drive exfiltration fails. Therefore, we presume that this delay was caused by the development of this new functionality.

Source	Refresh Token

Temporal analysis of exfiltrated data

We can also have a look at the metadata of the exfiltrated archives. What is rather unsurprising are the upload times which closely coincide with Burmese business hours – a smaller peak in the morning and a huge peak in the afternoon. Note that Myanmar is in UTC+6:30 time zone and China, presumed land of origin of Mustang Panda, is in UTC+8.

GDrive upload times in MM time (UTC+6:30)

What is more interesting are events produced by the group itself – transfers from Google Drive onto the distribution point and deletion of files from the distribution point. The huge peak is around 18:00 MM time which coincides with the end of the work day in Myanmar. The spread of starts of upload windows is negligible, leading us to the presumption that the transfer is automated. We have seen a few archives being placed in the wrong directories which could indicate that the tooling is still under development or there's still some manual work involved... Usually, the files have accumulated during the day on Google Drive and were transferred to the distribution point in the evening MM time.

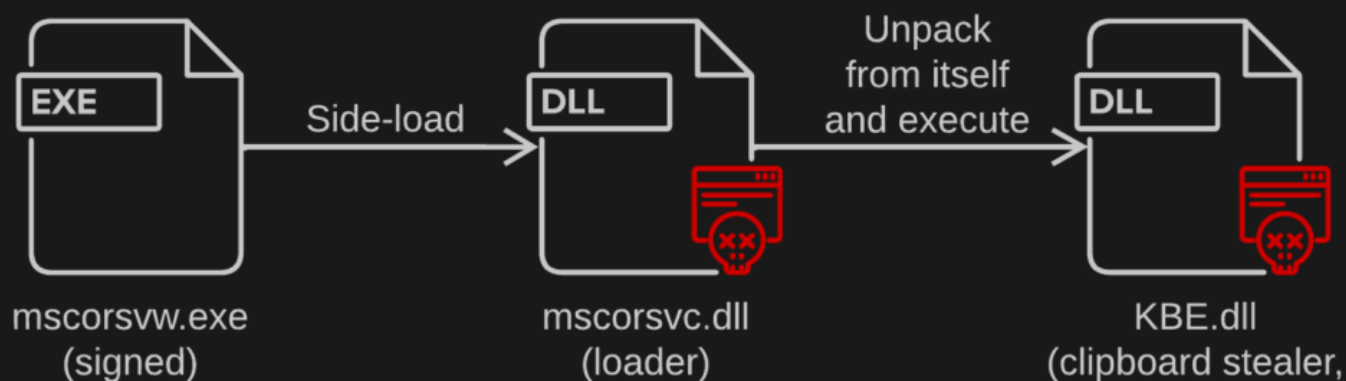

Stolen data transfer times in MM time (UTC+6:30)

As we already mentioned in the introduction of uncovered tools, we have found quite a lot of files that were “missing” something. By that we mean that on their own, they were either lacking communication functionality or implemented some techniques that were useless without being accompanied by another payload. Interestingly, while these were also using side-loading, they were not relying on external encrypted files, making their execution flow straightforward with 2-point graphs. For the sake of brevity, we will list these in a table:

Archive	Clean executable	SideLoaded DLL	Purpose (high-level)
MG/MG44	dabs.ex/44.ex	SensorAware.dll	fingerprinting/remote shell
AUD	mcsync.ex	mcaltlib.dll	audio recording
CHR	browser.ex	browser_elf.dll	Cookie dumping
T3YK	ygfdt.exe	corecrl.dll	remote shell

UC	melt_64.exe	libmlt-6.dll	UAC bypass
KKL/KKL1	mscorsvw.exe	mscorsvc.dll (contains KBE.dll)	clipboard stealer, keylogger

Archive KKL contained a straightforward stealer in KBE.dll that was also hard-coded (in an encrypted form) in mscorsvc.dll from which it was unpacked after side-loading. The newer KKL1 was practically the same.

There are also a few standalone files such as *x.exe* in archive *X* which composes logs of registry entries (Run), services, and scheduled tasks along with checking all signatures of executable files in *%WINDIR%*. Archive *NB* contains *nb.dat* which is just the *nbstat* utility executable. There was also a coinminer in the archive *INFO* along with its encrypted configuration file.

An interesting utility is DISK2 (and its variant DISKM); it is responsible for monitoring the system drive for any changes. Both are accompanied by a configuration file that defines which files are of interest and where such files should be copied to. It also notifies its C&C server about these files via an encrypted message over HTTP. There is also a version of this tool named *MF20211228* that

does not contain any configuration file and does not copy files anywhere, it just sends messages to the C&C server.

Contents of an archive DISK2. This toolset is responsible for monitoring the system drive for any changes in files defined by its configuration.

Oddballs in the collection

JSX

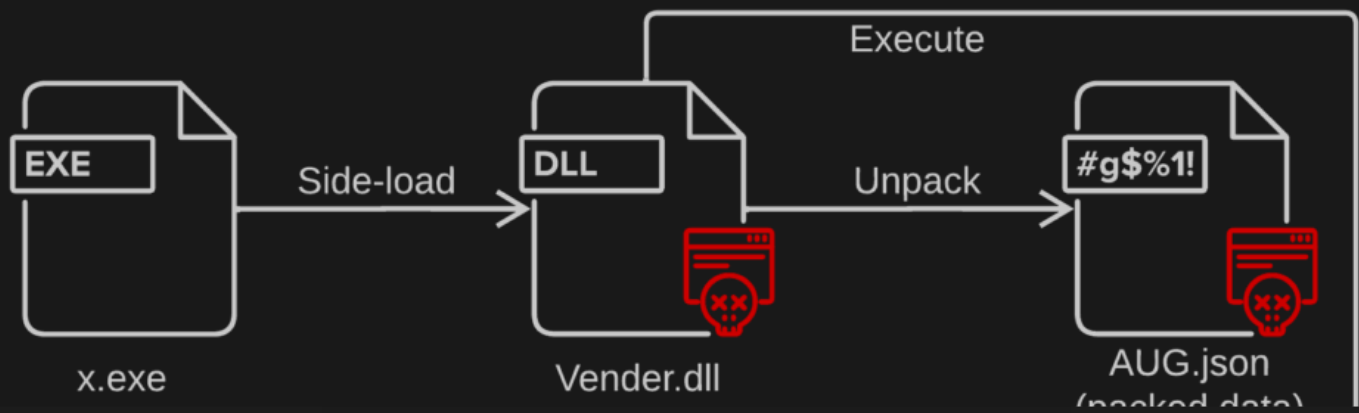

JSX archives (*JSX86* and newer *JSX861* for 32 bit version and *JSX64* and newer *JSX641* for 64 bit version) deserve a separate mention as they use a rather uncommon setup; a JavaScript file is at the beginning of the chain and instead of side-loading, the respective DLL is launched as a service. *mozload.dll* is a RAT written in Go that uses HTTPS and websockets for its communication. Interestingly, the RAT uses TLS Client Authentication; see Appendix A.1 and Appendix A.2 for the private key and the certificate.

The execution flow of the packages from JSX archives.

HT3

HT3 simply does not fall into any of the previous categories – it is a backdoor with external configuration accompanied with a shellcode loader and UAC bypass.

Execution flow of HT3. Note that it contains both 32 bit and 64 bit versions of an UAC bypass tool.

SE

Now we are finally getting to a more complex setup. These archives include several versions with very similar structures and sometimes with varying payloads. Functional changes are presented below; note that these do not include changes in side-loading which will be discussed later on. All versions feature a few evasion tricks that use registry tricks to hide files and file extensions.

Version	Version changes
SE1	Uses volume name for USB installer executable
SE3/SE4/SSE	Uses Delphi launcher (the one attributed to Mustang Panda), persistence integrated into <i>LPVDPOCX.OCX</i> (equivalent of <i>facesdk.dll</i> from <i>SE1</i>)
SE5	Uses volume name for USB installer executable, rollbacks to old USB installer
SE6	No significant functional changes
SE7	No significant functional changes

SE3 and therefore also *SE4* and *SSE* (which are mostly the same) use *vivaldi.exe* and *vivaldi_elf.dll* for its evasion module. Also, *FacialFeatureDemo.exe* and *facesdk.dll* are replaced by *Symantecs.exe* and *LDVPOCX.OCX*; the latter integrating persistence into itself instead of having it in a separate module. Interestingly, the USB installer has been replaced with one similar to the one in the archive *BMK*; a Delphi launcher that executes *Symantec.cmd* which is actually *Symantecs.exe*. These versions are also the only ones that have renamed 3 of 4 payload bundles (using *csdkset.dat* for backdoor, *EdrEpmcStorages.dat* for USB installer, and *PchEpmcStorages.dat* with *WTSAPI32.dll*). Confusingly, *WTSAPI32.dll* does not seem to be used anywhere and will be used for side-loading by later versions when the USB installer replacement is roll-backed.

SE6 and *SE7* abuse old Avast's proxy executable *wsc_proxy.exe* to side-load *wsc.dll* which serves as the dispatcher. Aside from this change, there are no other significant changes to the functionality.

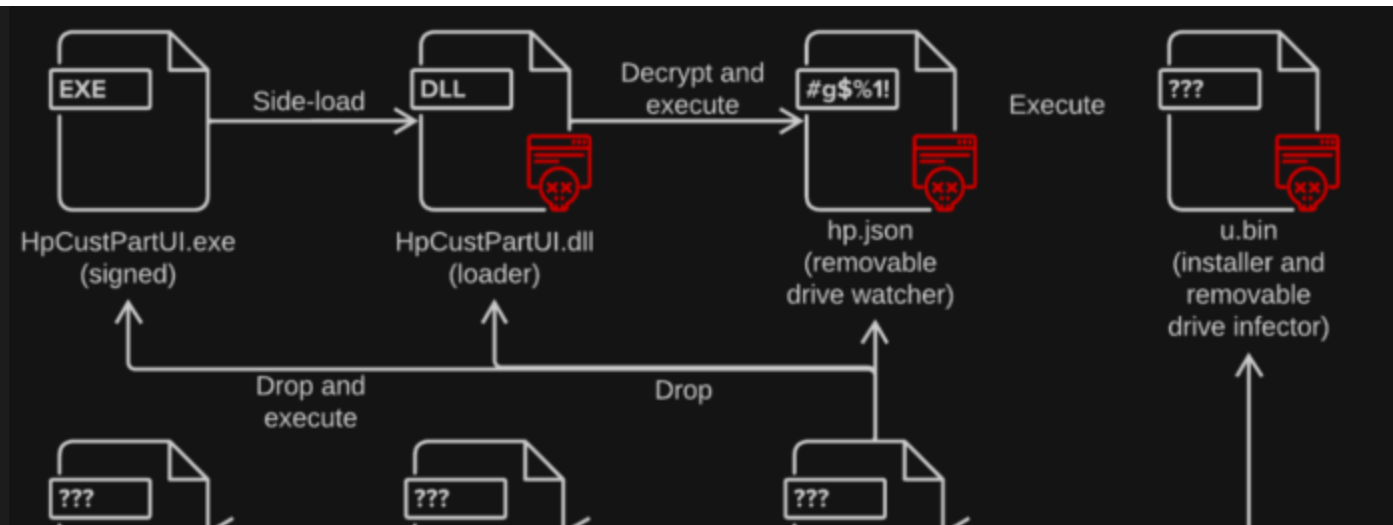

The schema of contents and the control flow of SE1. In newer versions, the persistence module is integrated in the dispatcher.

U5_2

The last complex toolset that we will present is from the archive *U5_2*. Most of the functional code is encrypted and bundled in *AtiVir.csc*. With the exception of a chain to a removable drive watcher, all the parts share similar XOR keys: *user_panda_%section_name%*; a rather interesting choice if the toolset really belongs to Mustang Panda.

An interesting part of the toolset is a file *install.exe* that reads a file from a given path, takes the serial number of the volume where the file is located, computes MD5 hash from the serial number and changes the first bytes of the file to the hex-encoded computed hash value.

The schema of contents and the control flow of U5_2.

Server infrastructure

The distribution point is an FTP server located in Malaysia that is accessible without a password (username *anonymous*, password is empty). We have also encountered a different FTP server in late 2020 containing very similar archives to the ones we now know contain exfiltrated data. Unfortunately, we did not have enough information to process the archives it contained. We presume that these two FTP servers were closely related or that even the current FTP server may be successor of the one we found previously.

We have noticed that the FTP server has stopped responding in October. Fortunately, the server itself was still alive and the distribution has migrated to using HTTP instead of FTP. They also started using HTTP Authorization; nevertheless, they have reused a weak username:password combination (123:123). This has caused a downtime of a few days in our tracking, but with a quick fix, we’ve managed to get back on track. Presumably, this might have been another attempt to foil our tracking attempts.

Our telemetry data also revealed another server in Russia. A client from Myanmar tried to download an archive XYZ from it via HTTP. Upon further inspection, the archive was found to be identical to XYZ from the aforementioned FTP server. We have tried to crawl the server for archives and files we have already seen on the FTP server and found the following toolsets:

Archive on the HTTP server	Matching archive on the FTP	Note
gdupiz.rar	GDU	Retrieved from our telemetry
xcrs.exe	X	Discovered by crawling
jsx861.rar	JSX861	Discovered by crawling

The fact that the affected client is from Myanmar, and the fact that the server contains some parts of the described toolset strongly indicates that it is part of the same campaign. Nevertheless, since at least one archive was renamed, we were unable to fully enumerate its contents. Similarly, we were not able to verify whether the server contains exfiltrated data.

C&C infrastructure

JSX RAT

The JSX RAT attempts to communicate with 103.169.90[.]132 using TLS client authentication. The certificate (see Appendix A.2) is hard-coded and we can try to use it to confirm related infrastructure. Looking at the server certificate data, we see that it imitates a real hosting company.

```
Common name:      blue.net
City, country:    San Francisco, CA, US
Fingerprint (sha1): e0adf667e287b0051988dda2b85e7541d7532703
Self-signed
```

Interestingly, the C&C's certificate had the exact same subject as the client certificate. Searching for other servers that use the same certificate yielded a couple more servers. Furthermore, we were able to confirm that the majority of these servers are running the same C&C software because they accept the RAT's hard-coded client certificate.

A server at 118.31.166[.]5 seems to be an outlier among these servers with port 4433 being exposed. Since it is the oldest one using the same certificate and the server exhibits the same communication traits on that port, we suspect that it might be a development server.

Two of these servers were open to RDP connections with a certificate that had *o9c[.]pg* as its CN (Common name). We tried to go further using these certificates to uncover further candidates for C&Cs. The timeline of uncovered servers is below:

Timeline of servers using the discovered certificates. Blue ones use a certificate with blue[.]net CN, red ones use o9c[.]pg as CN, purple ones have both. The highlighted line corresponds to JSX RAT C&C.

These are servers using the same certificate:

IP	Geo	Notes
103.169.90[.]132	MY	Original C&C Ports: 443, 22, 53, 3389
45.79.409[.]10	US	Suspected RAT C&C on port 443
118.31.166[.]5	CN	Suspected RAT C&C on port 443, different response codes
181.215.246[.]173	MY	
39.104.52[.]188	CN	Suspected RAT C&C on port 443
45.56.90[.]127	US	Suspected RAT C&C on port 443
154.204.176[.]249	HK	

47.244.2[.]17	HK	Suspected RAT C&C on port 443, RDP
47.96.236[.]105	CN	
134.122.129[.]170	HK	Suspected RAT C&C on port 443
172.105.158[.]102	US	Suspected RAT C&C on port 443, RDP
192.46.213[.]63	IN	Suspected RAT C&C on port 443

Overview on the servers with ties to JSX RAT C&C.

These are RDP servers sharing the same certificate as the two C&Cs with open RDP port:

IP	Geo	Notes
47.75.123[.]100	HK	
47.242.171[.]26	HK	
47.57.87[.]221	HK	
172.105.118[.]92	SG	
172.105.159[.]130	US	
47.244.2[.]17	HK	Is also on the previous list.
47.242.95[.]126	HK	
8.210.16[.]197	HK

Conclusion

It is not very often we stumble upon such a stash of samples that is used to distribute malware to infected devices; especially when we are talking about tools that are strongly correlated with a notorious APT group. We have shown links to multiple previously published research around

campaigns both using tools and TTPs, providing us with high confidence that the threat actor in question is Mustang Panda.

The exfiltrated data indicates that the toolsets that we have found were actively used around Myanmar. For instance, we have found audio recordings that corresponded to the audio recording tools we have identified in the archive named *AUD*. Although many tools were simplistic in their nature and sometimes also in chosen obfuscation methods, some archives contained tools which seem to deserve further analysis; be it due to their complexity or technical implementation.

What was really surprising was the sheer scale of the compromitation. We have identified many high-profile government targets, some opposition entities along with a few NGOs. It is worth noting that given the sheer volume of data and the language barrier, we have only been able to associate some of the victims with a specific organization. This means that the list of targets is likely incomplete and should be considered as approximate. Nevertheless, the daily rate of gigabytes of exfiltrated data should be enough to give a strong hint on the scale of the operation.

CryptoCore: Unmasking the Sophisticated Cryptocurrency Scam Operations

August 13, 2024 - by **Martin Chlumecký**

As digital currencies have grown, so have cryptocurrency scams, posing significant user risks. The rise of AI and deepfake technology has intensified scams exploiting famous personalities and events by creating realistic fake videos. Platforms like X and YouTube have been especially targeted, with...

Decrypted: DoNex Ransomware and its Predecessors

July 8, 2024 - by **Threat Research Team**

Researchers from Avast have discovered a flaw in the cryptographic schema of the DoNex ransomware and its predecessors. In cooperation with law enforcement organizations, we have been silently providing the decryptor to DoNex ransomware victims since March 2024. The cryptographic weakness was...

PC

New Diamorphine rootkit variant seen undetected in the wild

June 18, 2024 - by **David Álvarez**

Introduction Code reuse is very frequent in malware, especially for those parts of the sample that are complex to develop or hard to write with an essentially different alternative code. By tracking both source code and object code, we efficiently detect new malware and track the evolution of...
